(54) Title: THERAPEUTIC DELIVERY OF CARBON MONOXIDE

(57) Abstract: Metal carbonyls are used to deliver CO having biological activity, for example vasodilatation and inhibition of trans-plant rejection. The metal of the carbonyl is typically of groups 7 to 10, e.g. Fe and Ru. The carbonyl preferably has one or more ligands other than CO, such as amino acids, to modulate the CO release property and solubility.

**WO 02/092075 A2**

**Therapeutic Delivery of Carbon Monoxide****FIELD OF THE INVENTION**

The present invention relates to pharmaceutical  
5 compositions and compounds for the therapeutic delivery  
of carbon monoxide to humans and other mammals. Another  
use of the compositions and compounds is in organ  
perfusion.

**10 BACKGROUND OF THE INVENTION**

Carbon monoxide (CO) is, by common definition, a  
colorless, odorless, tasteless, non-corrosive gas of  
about the same density as that of air and is the most  
commonly encountered and pervasive poison in our  
15 environment. It is generally produced by the incomplete  
combustion of fossil fuels such as natural gas, propane,  
coal, gasoline and wood. In the atmosphere, the average  
global levels are estimated to be 0.19 parts per million  
(p.p.m.), 90% of which comes from natural sources  
20 including ocean micro-organism production, and 10% of  
which is generated by human activity. Thus, inhalation  
of even small quantities of CO is inevitable for living  
organisms.

Depending on the extent and time of exposure, CO is  
25 capable of producing a myriad of debilitating and  
harmful residual effects to the organism (1). The most  
immediate of these effects, and perhaps the most  
notorious one, is binding to hemoglobin in the blood  
stream, which rapidly decreases the oxygen transport  
30 capability of the cardiovascular system. Paradoxically,  
more than half a century ago it was found that CO is  
constantly formed in humans in small quantities (2), and  
that under certain pathophysiological conditions this

endogenous production of CO may be considerably increased (3-5). The discovery that hemoglobin, a heme-dependent protein, is required as substrate for the production of CO *in vivo* (6,7) and the identification of the enzyme heme oxygenase as the crucial pathway for the generation of this gaseous molecule in mammals (8) set the basis for the early investigation of an unexpected and still unrecognized role of CO in the vasculature (9). The succeeding cloning (10) and characterization of constitutive (HO-2) and inducible (HO-1) isoforms of heme oxygenase (11-13) as well as studies on the kinetics and tissue distribution of these enzymes (14) started to reveal a major importance of this pathway in the physiological degradation of heme. That is, the end products of heme degradation (CO, biliverdin and bilirubin) might possess, after all, crucial biological activities (15-17).

With regard to the cardiovascular system, the recognition that CO possesses vasodilatory properties (18-20) is, perhaps, the most significant evidence in favor of a pharmacological function of CO. Although the molecular mechanisms and the chemical modifications that are required to transduce the signals mediated by CO into a specific biological effect need to be fully elucidated, convincing scientific reports have recently highlighted the signaling properties of endogenously generated CO (21-24).

Experimental studies on the physiological effects of nitric oxide (NO) have been facilitated by the development of a wide variety of organic compounds that spontaneously release NO and can be easily acquired to reproduce a physiological or pathophysiological function of NO. There is now abundant literature on the different

types of NO donors and NO-releasing agents that, depending on their stability and half-life, can be used in disparate *in vitro* and *in vivo* models to simulate the biological activity of this important signaling molecule  
5 (25,26). In clinical practice, compounds that deliver NO into the circulation such as sodium nitroprusside and glyceryl trinitrate are used to lower blood pressure and treat certain cardiovascular diseases (27). Drugs containing a functional NO group that can selectively  
10 target an organ or tissue are currently being developed or are under clinical trials for the treatment of specific pathophysiological states (28,29). However, to date no compounds capable of delivering CO therapeutically have been identified.

15 US Patent 5,882,674 proposes administration of CO via transdermal delivery systems containing metal carbonyl complexes such as iron pentacarbonyl and iron enneacarbonyl. However, since this document provides no experimental data, and no description of specific  
20 devices, it is not clear how this proposal can be made to work. In particular it is not stated whether the iron carbonyl complex is intended to be absorbed from the patch, to release CO within the body, or whether the complex breaks down within the patch to release CO which  
25 then enters the bloodstream after absorption through the skin. If, and to the extent that, this document is considered to make available pharmaceutical devices, compositions and methods for the practical and effective delivery of carbon monoxide *in vivo*, such devices,  
30 compositions and methods are excluded from the scope of the present invention.

Amongst literature relating to metal carbonyls, WO98/48848 describes facial metal tricarbonyl compounds

and their use in the labelling of biologically active substrates. The metals, preferably radionuclides, are of Group 7, the metals identified being Mn, <sup>99m</sup>Tc, <sup>186</sup>Re and <sup>188</sup>Re. The compounds fac-[M(CO)<sub>3</sub>(OH<sub>2</sub>)<sub>3</sub>]<sup>+</sup> where M is  
5 the metal are proposed for labelling of biologically active substrates, as a result of which metal carbonyl compounds having a variety of biologically active ligands are obtained. In the examples radioactive Tc is used. The document describes preparation of diagnostic  
10 and therapeutic compositions but no therapeutic composition is specifically disclosed, nor is any treatment of any condition by therapy mentioned. There is no disclosure of use of the compounds for delivering carbon monoxide to physiological targets. If, and to  
15 the extent that, this document is regarded as disclosing a therapeutic use or mode of therapeutic administration of the carbonyl compounds, that subject matter is excluded from the scope of the present invention. Preferably the present invention excludes use of the  
20 facial carbonyl compounds disclosed in this document in any event.

WO 91/01128 and WO 91/01301 describe compositions for treating skin to repair the effects of photoaging by topical application or to treat acne or psoriasis by  
25 topical or oral administration. The active compounds are polyene esters and iron carbonyl complexes thereof. Specifically the iron of iron tri-carbonyl is coordinated to the polyene chain. No reason for including the iron carbonyl is mentioned. Insofar as  
30 therapeutic uses or compositions of carbonyl compounds are disclosed in these two documents, such uses and compositions are specifically excluded from the scope of the present invention.

WO 98/29115 describes compositions and methods for relaxing smooth muscle in a warm-blooded animal by administering certain transition metal nitrosyl compounds. Treatments of hypertension, angina pectoris, congestive heart failure and impotence are mentioned. Some of the compounds contain, in addition to NO, CO as a ligand. Specifically the CO-containing compound has the formula  $L_3M(NO)_yX_{3-y}$  where L is a two-electron Lewis base or  $L_3$  is a six-electron Lewis base, M is a Group 6 or 8 transition metal and when y is 1, X is carbon monoxide. The essential teaching of this document is concerned with the therapeutic effect of nitrosyl complexes. There is no disclosure that the CO ligand, when present, has any therapeutic effect by delivery of CO to a physiological target. The CO-containing metal nitrosyl complexes disclosed in it are excluded from the novel metal carbonyls of the present invention and their uses for treatments mentioned are also excluded from the present invention. Preferably transition metal nitrosyl complexes containing CO are excluded from the scope of the present invention in any event.

HU-B-211084 describes a composition, which is for oral administration, for the fortification of bones containing calcium phosphate, at least one calcium salt of an organic acid and optionally iron pentacarbonyl. The present invention does not extend to the use of iron pentacarbonyl in combination with calcium compounds as specified in this document in connection with the therapeutic uses and modes of administration described there, and preferably does not extend to the use of iron carbonyls and complexes including iron and CO in combination with calcium phosphates and/or calcium salts of organic acids in any event.

WO 95/05814 (US 6284752) and WO 00/56743 both disclose a very wide range of metal complexes, for use in treatment of disease relating to the overproduction of reactive oxygen species, particularly overproduction  
5 of NO. The stated aim is to modulate NO levels in the body by scavenging, or removing, NO *in situ*. The ex-vivo test data are stated to show that vasoconstriction is a direct result of the removal of endogenous nitric oxide. Carbon monoxide is mentioned as a possible  
10 ligand, but no example of a complex containing carbon monoxide is given and no effect is attributed to CO. Insofar as these documents are considered to disclose practical use of a complex containing CO for the specified purpose, such use does not form part of the  
15 present invention.

#### SUMMARY OF THE INVENTION

As exemplified by the experimental data detailed below, the present inventors have found that metal  
20 carbonyl compounds can be used to deliver CO to a physiological target so as to provide physiological effect.

Accordingly the present invention provides a pharmaceutical composition, for delivery of carbon  
25 monoxide to a physiological target, comprising a metal carbonyl compound or pharmaceutically acceptable salt thereof and at least one pharmaceutically acceptable carrier, wherein the metal carbonyl makes available CO suitable for physiological effect by at least one of the  
30 following means:

- 1) CO derived by dissociation of the metal carbonyl is present in the composition in dissolved form;

2) on contact with a solvent the metal carbonyl releases CO;

3) on contact with a tissue, organ or cell the metal carbonyl releases CO;

5        4) on irradiation the metal carbonyl releases CO.

Certain metal carbonyl compounds are capable of releasing CO on contact with a suitable solvent. When the pharmaceutical composition is to be administered in liquid form, this solvent may form a component part of the pharmaceutical composition. Thus in this aspect of  
10 the invention, the pharmaceutical composition contains CO derived from the metal carbonyl in dissolved form. The conditions under which the carbonyl compound is dissolved in the solvent during preparation of the  
15 pharmaceutical may be controlled such that the CO thus released is retained in solution. This may be facilitated where an equilibrium exists between the dissociated components and the undissociated carbonyl.

The dissociated components of the parent carbonyl  
20 may themselves be metal carbonyl complexes capable of releasing further CO. For example, when  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  is dissolved in DMSO, CO is liberated into solution, and a mixture of tri-carbonyl and di-carbonyl complexes is formed, and these themselves may be capable of releasing  
25 further CO.

In a further aspect of the invention, the pharmaceutical composition may not itself contain dissolved CO, but may be prepared such as to release CO on contact with a suitable solvent or medium. For  
30 example, the composition may contain a metal carbonyl compound capable of releasing CO on contact with water, e.g. on contact with an aqueous physiological fluid, such as blood or lymph. Alternatively, the

pharmaceutical composition may be intended to be dissolved in water prior to administration. Such pharmaceutical compositions may be prepared in solution or in solid form, such as in tablet form. If they are  
5 in solution form, they will typically be prepared in a solvent which does not support dissociation of the metal carbonyl compound, such that release of CO takes place only on contact with the appropriate solvent.

Alternatively or additionally, release of CO from  
10 the complex can be stimulated by reaction with a ligand in solution which for example replaces one of the ligands of the complex leading to loss of CO from the complex.

In another aspect of the invention the  
15 pharmaceutical composition may contain a metal carbonyl compound which releases CO on contact with a tissue, organ or cell. It is shown below that certain metal carbonyl compounds do not release CO to solution but are nevertheless capable of releasing CO to physiological  
20 cellular materials or tissues, such as vascular endothelium. For example,  $[\text{Fe}(\text{SPh})_2(2,2'\text{-bipyridine})(\text{CO})_2]$  is shown below not to release CO to myoglobin in solution, but is nevertheless capable of promoting dilatation of pre-contracted aortic rings.  
25 Without wishing to be limited by any particular theory, it is thought that CO may be released from such compounds as a result of an oxidation-reduction reaction, mediated by cellular components such as cytochromes.

30 However the invention is not limited to a redox reaction as a mechanism for CO release, since loss of at least a first CO from the complex may occur without redox.

In a further aspect of the invention, the pharmaceutical composition may contain a metal carbonyl compound which releases CO on irradiation. The compound may be irradiated prior to administration, for example  
5 to produce a solution of dissolved CO, or may be irradiated *in situ* after administration. It is contemplated that such compositions may be used to provide controlled, localised release of CO. For example a pharmaceutical composition of this type may be  
10 administered during surgery, and CO released specifically at a site in need thereof, e.g. to induce vasodilation, by localised irradiation by means of a laser or other radiant energy source, such as UV rays.

Typically the pharmaceutical compositions of the present invention release CO such as to make it  
15 available to a therapeutic target in dissolved form. However, in some circumstances CO may be released from a metal carbonyl directly to a non-solvent acceptor molecule.

20 It will be apparent that pharmaceutical compositions according to the present invention may be capable of delivering CO therapeutically through one or more of the above described modes of action.

Typically the metal carbonyl compound comprises a  
25 complex of a transition metal, preferably a transition metal from group 7 or groups 8 to 10 (in this specification the groups of the periodic table are numbered according to the IUPAC system from 1 to 18). The number of carbonyl ligands is not limited, provided  
30 at least one carbonyl ligand is present. The preferred metals are transition metals of lower molecular weight, in particular Fe, Ru, Mn, Co, Ni, Mo and Rh. Two other metals which may be used are Pd and Pt. In the metal

carbonyl complexes used in the invention, the metal is typically in a low oxidation state, i.e. 0, I or II. For the metals preferred, the oxidation states are typically not higher than  $\text{Fe}^{\text{II}}$ ,  $\text{Ru}^{\text{II}}$ ,  $\text{Mn}^{\text{I}}$ ,  $\text{Co}^{\text{II}}$  preferably  $\text{Co}^{\text{I}}$ ,  $\text{Rh}^{\text{III}}$  preferably  $\text{Rh}^{\text{I}}$ ,  $\text{Ni}^{\text{II}}$ ,  $\text{Mo}^{\text{II}}$ . The metal is preferably not a radionuclide. Fe is one particularly suitable metal, since Fe is present in quantity in mammals.

The metal carbonyl compounds may be regarded as complexes, because they comprise CO groups coordinated to a metal centre. However the metal may be bonded to other groups by other than coordination bonds, e.g. by ionic or covalent bonds. Thus groups other than CO which form part of the metal carbonyl compound need not strictly be "ligands" in the sense of being coordinated to a metal centre via a lone electron pair, but will be referred to herein as "ligands" for ease of reference.

Thus, the ligands to the metal may all be carbonyl ligands, as e.g. in  $[\text{Mn}_2(\text{CO})_{10}]$ . Alternatively, the carbonyl compound may comprise at least one modulatory ligand. By this is meant a ligand which is not CO, but which modulates a particular property of the complex, such as the tendency to release CO, solubility, hydrophobicity, stability, electrochemical potential, etc. Thus suitable choices of ligand may be made in order to modulate the behaviour of the compound. For example it may be desirable to modulate the solubility of the compound in organic and/or aqueous solvents, its ability to cross cell membranes, its rate of release of CO on contact with a particular solvent or cell type, or on irradiation, etc.

Such ligands are typically neutral or anionic ligands, such as halide, or derived from Lewis bases and

having N, P, O or S or a conjugated carbon group as the coordinating atom(s). Preferred coordinating atoms are N, O and S. Examples include, but are not limited to, sulfoxides such as dimethylsulfoxide, natural and synthetic amino acids and their salts for example, glycine, cysteine, and proline, amines such as  $\text{NEt}_3$  and  $\text{H}_2\text{NCH}_2\text{CH}_2\text{NH}_2$ , aromatic bases and their analogues, for example, bi-2,2'-pyridyl, indole, pyrimidine and cytidine, pyrroles such as biliverdin and bilirubin, drug molecules such as YC-1 (2-(5'-hydroxymethyl-2'-furyl)-1-benzylindazole), thiols and thiolates such as  $\text{EtSH}$  and  $\text{PhSH}$ , chloride, bromide and iodide, carboxylates such as formate, acetate, and oxalate, ethers such as  $\text{Et}_2\text{O}$  and tetrahydrofuran, alcohols such as  $\text{EtOH}$ , and nitriles such as  $\text{MeCN}$ . Particularly preferred are coordinating ligands, such as amino acids, which render the carbonyl complex stable in aqueous solution. Other possible ligands are conjugated carbon groups, such as dienes. One class of ligands which can provide metal carbonyl compounds of use in this invention is cyclopentadiene ( $\text{C}_5\text{H}_5$ ) and substituted cyclopentadiene. The substituent group in substituted cyclopentadiene may be for example an alkanol, an ether or an ester, e.g. - $(\text{CH}_2)_n\text{OH}$  where n is 1 to 4, particularly - $\text{CH}_2\text{OH}$ , - $(\text{CH}_2)_n\text{OR}$  where n is 1 to 4 and R is hydrocarbon preferably alkyl of 1 to 4 carbon atoms and - $(\text{CH}_2)_n\text{OOCR}$  where n is 1 to 4 and R is hydrocarbon preferably alkyl of 1 to 4 carbon atoms. The preferred metal in such a cyclopentadiene or substituted cyclopentadiene carbonyl complex is Fe. Preferably the cyclopentadiene carbonyl complex is cationic, being associated with an anion such as chloride.

As mentioned above certain metal nitrosyl complexes disclosed in WO 98/29115 and their uses disclosed are excluded from the present invention, and preferably the invention does not extend to metal carbonyl complexes containing NO (nitrosyl) in any event. Furthermore as mentioned above certain iron carbonyl complexes disclosed in WO 91/01128 and WO 91/01301 and their uses disclosed therein are excluded from the present invention. Preferably the invention does not extend to topical or oral administration of iron carbonyl polyene complexes, nor to these complexes in themselves.

A further exclusion from the present invention are the Mn and radionuclide complexes disclosed in WO 98/48848. Preferably the present invention excludes therapeutic use of these Mn complexes. Preferably the invention excludes carbonyls of radioactive metals, in any case.

CO is suggested to act at least in part through the stimulation of guanylate cyclase activity. Thus the metal carbonyl compound may desirably comprise ligands which modulate the effect of CO on guanylate cyclase. For example, the drug YC-1 (3-(5'-hydroxymethyl-2'-furyl)-1-benzylindole) is thought to enhance stimulation of guanylate cyclase by CO. Thus incorporation of ligands such as YC-1 or derivatives thereof into the metal carbonyl compounds can alter or enhance the biological effects of the released CO.

Thus the properties of pharmaceutical compositions of the present invention may be tailored as required by appropriate choice of metal centres and number and type of associated ligands in the metal carbonyl compound.

The metal carbonyl compound may further comprise a targeting moiety, to facilitate release of CO at an

appropriate site. The targeting moiety is typically capable of binding a receptor on a particular target cell surface, in order to promote release of CO at the required site. The targeting moiety may be a part of a modulating ligand capable of binding to a receptor found on the surface of the target cells, or may be derived from another molecule, such as an antibody directed against a particular receptor, joined to the complex by a suitable linker.

The present invention also provides a pharmaceutical composition for delivery of CO, comprising as active ingredient a compound of the formula  $M(CO)_x A_y$  where x is at least one, y is at least one, M is a metal, A is an atom or group bonded to M by an ionic, covalent or coordination bond, and, in the case where  $y > 1$ , each A may be the same or different, or a pharmaceutically acceptable salt of such a compound. Typically, M is a transition metal, particularly of group 7 or groups 8 to 10, and A may be selected from halogens, groups having N, P, O or S atoms providing lone electron pairs for coordination bonding to M, and conjugated carbon groups. More details of preferred metals and ligands are given above. The carbonyl complex should be pharmaceutically acceptable, in particular non-toxic or of acceptable toxicity at the dosage levels envisaged.

The pharmaceutical compositions of the present invention typically comprise a pharmaceutically acceptable excipient, carrier, buffer, stabiliser or other materials well known to those skilled in the art. Such materials should be non-toxic and should not interfere unduly with the efficacy of the active ingredient. The precise nature of the carrier or other

material may depend on the route of administration, e.g. oral, intravenous, subcutaneous, nasal, intramuscular, intraperitoneal, or suppository routes.

Pharmaceutical compositions for oral administration  
5 may be in tablet, capsule, powder or liquid form. A tablet may include a solid carrier such as gelatin or an adjuvant or a slow-release polymer. Liquid pharmaceutical compositions generally include a liquid carrier such as water, petroleum, animal or vegetable  
10 oils, mineral oil or synthetic oil. Physiological saline solution, dextrose or other saccharide solution or glycols such as ethylene glycol, propylene glycol or polyethylene glycol may be included. Pharmaceutically acceptable amounts of other solvents may also be  
15 included, in particular where they are required for dissolving the particular metal carbonyl compound contained in the composition.

For intravenous, cutaneous or subcutaneous injection, or injection at the site of affliction, the  
20 active ingredient will typically be in the form of a parenterally acceptable solution which is pyrogen-free and has suitable pH, isotonicity and stability. Those of relevant skill in the art are well able to prepare suitable solutions using, for example, isotonic vehicles  
25 such as Sodium Chloride Injection, Ringer's Injection, Lactated Ringer's Injection. Preservatives, stabilisers, buffers, antioxidants and/or other additives may be included, as required. Delivery systems for needle-free injection are also known, and  
30 compositions for use with such systems may be prepared accordingly.

Administration is preferably in a prophylactically effective amount or a therapeutically effective amount

(as the case may be, although prophylaxis may be considered therapy), this being sufficient to show benefit to the individual. The actual amount administered, and rate and time-course of administration, will depend on the nature and severity of what is being treated. Prescription of treatment, e.g. decisions on dosage etc, is within the responsibility of general practitioners and other medical doctors, and typically takes account of the disorder to be treated, the condition of the individual patient, the site of delivery, the method of administration and other factors known to practitioners. Examples of the techniques and protocols mentioned above can be found in Remington's Pharmaceutical Sciences, 16th edition, Osol, A. (ed), 1980.

When formulating pharmaceutical compositions according to the present invention, the toxicity of the active ingredient and/or the solvent must be considered. The balance between medical benefit and toxicity should be taken into account. The dosages and formulations of the compositions will typically be determined so that the medical benefit provided outweighs any risks due to the toxicity of the constituents.

There is further provided a method of introducing CO to a mammal comprising the step of administering a pharmaceutical composition according to the present invention. CO is thought to act at least in part through stimulation or activation of guanylate cyclase. CO is thought to have functions as, inter alia, a neurotransmitter and a vasodilating agent. Accordingly there is provided a method of delivering CO to a mammal for stimulation of guanylate cyclase activity. There is further provided a method of delivering CO to a mammal

for stimulating neurotransmission or vasodilation. However the present applicants do not wish to be bound by theory and do not exclude the possibility that CO operates by other mechanisms.

5           The heme oxygenase 1 (HO-1) pathway is thought to represent a pivotal endogenous inducible defensive system against stressful stimuli including UVA radiations, carcinogens, ischaemia-reperfusion damage, endotoxic shock and several other conditions

10 characterised by production of oxygen free radicals (30-32). The protective effect of HO-1 is attributed to the generation of the powerful antioxidants biliverdin and bilirubin and the vasoactive gas CO. Expression of HO-1 has been linked with cardiac xenograft survival (33),

15 suppression of transplant arteriosclerosis (34) and amelioration of post-ischemic myocardial dysfunction (35). HO-1 has also been directly implicated in the resolution phase of acute inflammation in rats (36). Other pathological situations, such as haemorrhagic

20 shock in brain and liver as well as sepsis (37-39), are characterized by induction of the HO-1 gene, which seems to play a crucial role in counteracting the vascular dysfunction caused by these pathophysiological states. Increased generation of CO as a consequence of HO-1

25 induction markedly affects vessel contractility and diminishes acute hypertension in the whole organism (23,40). Exposure of animals to ambient air containing low concentrations of CO or transfection of the HO-1 gene results in protection against hyperoxia-induced

30 lung injury *in vivo*, a mechanism mediated by attenuation of both neutrophil inflammation and lung apoptosis (cell death) (41,42). Exogenous CO gas also has the ability to suppress pro-inflammatory cytokines and modulate the

expression of the anti-inflammatory molecule, IL-10, both *in vitro* and *in vivo* (43). Therefore administration of CO in accordance with the invention may be used for treatment of any of these conditions, for modulation of inflammatory states and regression of other pathophysiological conditions including cancer.

Accordingly there is provided a method of introducing CO to a mammal comprising the step of administering a pharmaceutical composition according to the present invention, for treatment of hypertension, such as acute, pulmonary and chronic hypertension, radiation damage, endotoxic shock, inflammation, inflammatory-related diseases such as asthma and rheumatoid arthritis, hyperoxia-induced injury, apoptosis, cancer, transplant rejection, arteriosclerosis, post-ischemic organ damage, myocardial infarction, angina, haemorrhagic shock, sepsis, penile erectile dysfunction and adult respiratory distress syndrome.

The present invention also provides the use of a metal carbonyl compound as herein described in the manufacture of a medicament for delivering CO to a physiological target, particularly a mammal, to provide a physiological effect, e.g. for stimulating neurotransmission or vasodilation, or for treatment of any of hypertension, such as acute, pulmonary and chronic hypertension, radiation damage, endotoxic shock, inflammation, inflammatory-related diseases such as asthma and rheumatoid arthritis, hyperoxia-induced injury, apoptosis, cancer, transplant rejection, arteriosclerosis, post-ischemic organ damage, myocardial infarction, angina, haemorrhagic shock, sepsis, penile erectile dysfunction and adult respiratory distress

syndrome. Such medicaments may be adapted for administration by an oral, intravenous, subcutaneous, nasal, inhalatory, intramuscular, intraperitoneal or suppository route. Preferably the present invention  
5 excludes delivery of a metal carbonyl or a decomposition product thereof to an organism through the skin or mucosa.

The invention further provides use of the metal carbonyls here described in treatment, e.g. by  
10 perfusion, of a viable mammalian organ extracorporeally, e.g. during storage and/or transport of an organ for transplant surgery. For this purpose, the metal carbonyl is in dissolved form, preferably in an aqueous solution. The viable organ may be any tissue containing  
15 living cells, such as a heart, a kidney, a liver, a skin or muscle flap, etc.

The invention also consists in a metal carbonyl compound of the formula

$M(CO)_x A_y B_z$  where  
20 M is Fe, Co or Ru,  
x is at least one,  
y is at least one,  
z is zero or at least one,  
each A is a ligand other than CO and is monodentate  
25 or polydentate with respect to M and is selected from the amino acids  
alanine  
arginine  
asparagine  
30 aspartic acid  
cysteine  
glutamic acid  
glutamine

glycine  
histidine  
isoleucine  
leucine  
5 lysine  
methionine  
phenylalanine  
proline  
serine  
10 threonine  
tryptophan  
tyrosine  
valine

$O(CH_2COO)_2$  and  
15  $NH(CH_2COO)_2$ , and  
B is optional and is a ligand other than CO,  
excluding  $Fe(CO)_x A_y$  where A is cysteine or an ester  
of cysteine and  $Ru(CO)_x A_y$  where A is proline.

x is preferably 3, y is preferably 1 and z is  
20 preferably 1.

The term amino acid here used includes the species  
obtained by loss of the acidic hydrogen, such as  
glycinato.

$B_z$  represents one or more optional other ligands.  
25 There are no particular limitations on B, and ligands  
such as halides, e.g. chloride, bromide, iodide, and  
carboxylates, e.g. acetate may be used.

M is selected from Fe, Ru and Co. These metals are  
preferably in low oxidation states, as described above.

30 Use of the known iron compounds  $[Fe(SPh)_2(2,2'$ -  
bipyridine) $(CO)_2]$  and  $[Fe(SPh)_2(NH_2CH_2CH_2NH_2)(CO)_2]$  is also  
envisaged in this invention.

It is further considered that, in place of the metal carbonyl compounds discussed above, the pharmaceutical compositions of the present invention may comprise oxalate compounds, formic acid, or formate compounds, which may likewise deliver CO to a physiological target. For example, bis-(2,4-dinitrophenyl) oxalate is known to decompose in water to liberate CO into solution. Therefore the present invention further provides a pharmaceutical composition, for delivery of carbon monoxide to a physiological target, comprising formic acid, a formate, a formate ester or amide, an oxalate, or an oxalate ester or amide, or a pharmaceutically acceptable salt thereof and at least one pharmaceutically acceptable carrier, wherein the formic acid, formate or oxalate or amide or ester makes available CO suitable for physiological effect.

It is thought that the nitrophenyl groups of bis-(2,4-dinitrophenyl) oxalate are good leaving groups, because of the electron-withdrawing effects of the nitro groups, and that this may promote the decomposition of the oxalate to yield CO.

It is therefore considered that oxalates or formates having in which the acid groups are linked, e.g. by an ester bond, to aromatic groups with electron-withdrawing substituents, such as tosyl groups, are particularly suitable for use in pharmaceutical compositions according to the present invention.

There is further provided a method of introducing carbon monoxide to a mammal comprising the step of administering a pharmaceutical composition comprising formic acid, a formate, a formate ester or amide or an oxalate, an oxalate ester or amide, or a

pharmaceutically acceptable salt thereof, and at least one pharmaceutically acceptable carrier.

All the above discussion and disclosure relating to metal carbonyl compounds is also considered to relate to  
5 formic acid, formates, oxalates and formate or oxalate amides and esters.

Throughout this application, references to medical treatment are intended to include both human and veterinary treatment, and references to pharmaceutical  
10 compositions are accordingly intended to encompass compositions for use in human or veterinary treatment.

#### INTRODUCTION OF THE DRAWINGS

Experimental data illustrating the present  
15 invention will now be described by reference to the accompanying figures, in which:

Figure 1 shows apparatus for measuring release of CO by metal carbonyl complexes on irradiation and structures of  $[\text{Mn}_2(\text{CO})_{10}]$  and  $[\text{Fe}(\text{CO})_5]$ .

20 Figure 2 shows deoxy-myoglobin and CO-myoglobin absorption spectra.

Figure 3 shows NMR spectra illustrating the dissolution of  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  in DMSO.

25 Figure 4 shows viability data for cells treated with metal carbonyl compounds.

Figure 5 shows relaxation of aortic rings on treatment with metal carbonyl complexes.

Figure 6 shows the effects of various treatments on perfused rat hearts.

30 Figure 7 shows expression of heme oxygenase 1 in rat hearts.

Figure 8 shows the effects of various treatments on rat mean arterial pressure.

Figures 9a to 9f are tables presenting CO release data of metal carbonyl complexes.

Figure 10 is a graph showing survival rates in a transplant rejection study described below.

5 Figure 11 is a graph of nitrite produced in a study of NO production in macrophages described below.

Figure 12 is graphs of cell viability in the study of NO production in macrophages.

## 10 EMBODIMENTS OF THE INVENTION AND EXPERIMENTAL DATA

For the experiments here described, iron pentacarbonyl,  $[\text{Fe}(\text{CO})_5]$ , dimanganese decacarbonyl,  $[\text{Mn}_2(\text{CO})_{10}]$ , tricarbonyldichlororuthenium (II) dimer,  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$ , and ruthenium(III) chloride hydrate,  $\text{RuCl}_3$ ,  
15 were purchased from Sigma-Aldrich Company Ltd. (Poole, Dorset, UK). Other carbonyl complexes have been synthesized, as described below. Stock solutions of metal carbonyl complexes were prepared fresh prior to each experiment by dissolving the compounds in dimethyl  
20 sulfoxide (DMSO), water or saline. Hemin (ferriprotoporphyrin IX chloride) and tin protoporphyrin IX ( $\text{SnPPiX}$ ) were from Porphyrin Products Inc. (Logan, Utah, USA). Stock solutions of both porphyrins were prepared by dissolving the compounds in 0.1 M NaOH and  
25 then adjusting the pH to 7.4 by addition of 0.01 M phosphate buffer. The guanylate cyclase inhibitor,  $[1\text{H}-[1,2,4]\text{Oxadiazole}[4,3-\text{a}]\text{quinoxalin-1-one}]$  (ODQ), was obtained from Alexis Corporation (Bingham, Nottingham, UK) and polyclonal rabbit anti-HO-1 antibodies were  
30 purchased from Stressgen (Victoria, Canada). Horse heart myoglobin,  $\text{N}^G$ -nitro-L-arginine methyl ester (L-NAME) and all other reagents were from Sigma, unless otherwise specified.

All data are expressed as mean  $\pm$  s.e.m. Differences between the groups analysed were assessed by the Student's two-tailed *t*-test, and an analysis of variance (ANOVA) was performed where more than two treatments were compared. Results were considered statistically significant at  $P < 0.05$ .

**A. Detection of CO liberated from transition metal carbonyl complexes.**

The release of CO from metal carbonyl complexes was assessed spectrophotometrically by measuring the conversion of deoxymyoglobin (deoxy-Mb) to carbonmonoxy myoglobin (MbCO). MbCO has a distinctive absorption spectrum between 500 and 600 nm, and changes at 540 nm were used to quantify the amount of CO liberated. Myoglobin solutions (66  $\mu$ M final concentration) were prepared freshly by dissolving the protein in 0.04 M phosphate buffer (pH 6.8). Sodium dithionite (0.1 %) was added to convert myoglobin to deoxy-Mb prior to each reading. All the spectra were measured using a Helios  $\alpha$  spectrophotometer.

Direct addition of iron pentacarbonyl,  $[\text{Fe}(\text{CO})_5]$ , or dimanganese decacarbonyl,  $[\text{Mn}_2(\text{CO})_{10}]$ , to myoglobin solutions did not result in any appreciable formation of carbonmonoxy myoglobin (MbCO) over time (data not shown). This is consistent with the notion that these two transition metal carbonyl complexes do not release CO unless stimulated by light (44,45). Therefore release of CO was induced by exposing these metal carbonyl complexes to a cold light source and allowing the gas to diffuse through a membrane before reacting with myoglobin as shown in Figure 1.

Five hundred microliters of iron pentacarbonyl ( $[\text{Fe}(\text{CO})_5]$ , 99.9%) or 1 ml of dimanganese decacarbonyl ( $[\text{Mn}_2(\text{CO})_{10}]$ , 13 mM in DMSO) (see also chemical structure) were placed as carbonyl solution 2 in a plastic tube 1. A cell culture insert 3 (Costar) was sealed on top in order to create two separate chambers with a 0.6 cm air space between the solution 2 and an insert membrane 6 (Anapore™ 0.4  $\mu\text{m}$ ). 1.5 ml of deoxy-Mb solution (66  $\mu\text{M}$ ) was placed in the insert which was covered with Parafilm™ 5. The carbonyl solution was then exposed to cold light from a source 7 to stimulate CO release, allowing the gas to diffuse through the membrane 6 into the myoglobin solution 4. Aliquots of the myoglobin solution 4 were taken at different times and the conversion of deoxy-Mb to MbCO measured spectrophotometrically.

The spectral change on transition from deoxy-Mb to MbCO was measured by bubbling CO gas to a solution of deoxy-Mb (Figure 2a). Upon illumination,  $[\text{Fe}(\text{CO})_5]$  and  $[\text{Mn}_2(\text{CO})_{10}]$  produced a similar change in the absorbance spectrum of myoglobin, with a gradual increase in MbCO formation observed over time; in both cases the distinctive identified spectra were the ones typical of MbCO (Figures 2b and 2c). Under the experimental conditions used, a complete saturation of the myoglobin solution was achieved by  $[\text{Mn}_2(\text{CO})_{10}]$  (13  $\mu\text{mol/ml}$ ) in approximately 40 min of continuous exposure to light (Figure 2d).

Various metal carbonyl complexes were tested for their ability to elicit MbCO formation when added directly to a deoxy-Mb solution. To different extents,  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$ ,  $[\text{Ru}(\text{CO})_2(\text{DMSO})_2\text{Cl}_2]$ ,  $[\text{Ru}(\text{CO})_3\text{Cl}_2(\text{cytosine})]$  and  $[\text{Ru}(\text{CO})_3(\text{glycinate})\text{Cl}]$  all released CO when added

directly to the Mb solution. No MbCO was detected in the case of  $[\text{Fe}(\text{SPh})_2(2,2'\text{-bipyridine})(\text{CO})_2]$  and  $[\text{Fe}(\text{SPh})_2(\text{H}_2\text{NCH}_2\text{CH}_2\text{NH}_2)(\text{CO})_2]$ , but as shown below both these compounds provided a vasodilatory effect.

5        Data for the tricarbonyldichlororuthenium (II) dimer  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  are shown in Figure 2e. The metal carbonyl complex was solubilized in DMSO (9.7 mM stock solution), aliquots of 2 to 32  $\mu\text{l}$  were added directly to 1 ml of deoxy-Mb solutions (66  $\mu\text{M}$ ) and absorption  
10       spectrum determined immediately after mixing the samples by inversion. A linear regression analysis of the saturation curve of MbCO revealed that for each mole of  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  approximately 0.7 moles of CO are liberated (Figure 2f).

15       Further data on release of CO measured by the same test procedure is described in section H below.

#### **B. NMR studies of $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$**

Further studies were conducted on the chemistry of transition metal carbonyls using NMR spectroscopy. The  
20        $^{13}\text{C}$  NMR spectrum showed that  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  freshly dissolved in DMSO does not exist as a dimer; in fact, two distinct sets of signals corresponding to the known tri-carbonyl (1) and di-carbonyl (2) monomers (see  
25       formulae in Fig. 3) could be identified. The NMR analysis reveals that, during the solubilization process, DMSO acts as a coordinated ligand to ruthenium thereby promoting the formation of the monomers.

Figure 3a shows a 100.62 MHz  $^{13}\text{C}\{^1\text{H}\}$  NMR spectrum  
30       taken during the first 23 min of the reaction between freshly prepared  $[\text{RuCl}_2(\text{CO})_3]_2$  and  $d_6\text{-DMSO}$ . The solution very slowly produced fine bubbles of a gas, presumably CO, implied by the formation of compound 2. When the

experiment was repeated by dissolving initially the metal complex in DMSO and then diluting with  $\text{CDCl}_3$ , the assignment of the signals coincided with the published  $^{13}\text{C}(\text{CO})$  chemical shifts of fac- $[\text{RuCl}_2(\text{CO})_3(\text{DMSO})]$  (1,  $\delta$  183.0, 186.8), cis, cis, trans- $[\text{RuCl}_2(\text{CO})_2(\text{DMSO})_2]$  (2,  $\delta$  185.0) and cis, cis, cis- $[\text{RuCl}_2(\text{CO})_2(\text{DMSO})_2]$  (3,  $\delta$  186.0, 191.9) (46). Figure 3b shows a 100.62 MHz  $^{13}\text{C}\{^1\text{H}\}$  NMR spectrum taken after  $[\text{RuCl}_2(\text{CO})_3]_2$  in  $d_6$ -DMSO was warmed at 50 °C for 5 min and left to accumulate overnight. In addition to the peaks that could be assigned to compounds 1, 2 and 3, there are carbonyl signals at  $\delta$  187.9 and 190.5 due to unidentified species.

The detection of di-carbonyl monomers demonstrates that CO is liberated; the  $^{13}\text{C}$  NMR spectrum also suggests that the ratio between compounds 1 and 2 is 40:60.

In sections C and D below, we refer for convenience to  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$ , but as explained here, when dissolved in DMSO other species are actually present.

20

### **C. Effect of $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$ on cell viability**

As there are no precedent studies on the use of metal carbonyl complexes in biological systems, it was necessary to evaluate the potential cytotoxic effect of these compounds. Therefore, the viability of cells in culture was determined after short or prolonged exposure to various concentrations of metal carbonyls.

Rat vascular smooth muscle cells were obtained from the Coriell Cell Repository (Camden, NJ, USA) and grown in Dulbecco's Minimal Essential Medium (MEM) supplemented with 20% foetal calf serum, 2 x MEM vitamins, 2 x MEM non-essential and essential amino acids, penicillin (100 units/ml) and streptomycin (0.1

mg/ml). Confluent cells were treated with different concentrations of metal carbonyl (introduced as DMSO solution - see section B) for various times and cell viability was assessed using a colorimetric assay kit from Promega (Madison, WI, USA) as previously described (47) after 3 or 24 h incubation, or after 3 h exposure to the agents followed by 21 h incubation in complete media. Results are expressed as the mean  $\pm$  s.e.m. of 6 independent experiments and differences were considered statistically significant at  $P < 0.05$  (\*).

Exposure of  $[\text{Fe}(\text{CO})_5]$  to light gradually resulted in deposition of a green-brown precipitate, and so viability studies on this metal carbonyl were not pursued. Nevertheless,  $[\text{Fe}(\text{SPh})_2(2,2'\text{-bipyridine})(\text{CO})_2]$  proved to elicit a marked vasodilatory effect (see below).

As shown in Figure 4b, treatment of vascular smooth muscle cells for 3 h with  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  (0-420  $\mu\text{M}$  final concentration) did not promote any detectable cytotoxicity. Similarly, cell viability was well preserved after exposure to this metal carbonyl for 3 h followed by an additional 21 h incubation in complete medium. A pronounced cytotoxic effect (>50% loss in cell viability) was only apparent after prolonged exposure (24 h) to very high concentrations (> 400  $\mu\text{M}$ ) of  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$ .

Treatment of cells with the same amounts of vehicle (DMSO) or equivalent molar concentrations of ruthenium ( $\text{RuCl}_3$ ) did not cause any appreciable decrease in cell viability over time (Figure 4a and 4c, respectively) indicating that neither the vehicle nor the metal are responsible for the observed cytotoxic effect of  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$ .

In the case of  $[\text{Mn}_2(\text{CO})_{10}]$  (0-100  $\mu\text{M}$ ), no major cytotoxicity on smooth muscle cells was detected after exposure for 24 h in complete medium (data not shown).

5 **D. Vasodilatory effect of CO released from  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$**

It has previously been demonstrated that increased endogenous CO as a result of HO-1 induction in rat aortas markedly attenuates vasoconstriction (23). To investigate whether CO released from metal carbonyl  
10 complexes evokes specific biological activities, we first assessed the effect of these complexes on vessel contractility using the isolated aortic ring model.

Transverse ring sections of thoracic aorta were isolated from male Lewis rats and suspended under a 2 g  
15 tension in an organ bath containing oxygenated Krebs-Henseleit buffer at 37 °C as previously described (23). The relaxation response to cumulative doses of metal carbonyl (dissolved in DMSO - see section B) was assessed in aortic rings pre-contracted with  
20 phenylephrine (3  $\mu\text{M}$ ). Control rings were similarly treated by adding equal doses of DMSO (vehicle) to the organ bath. Results are shown in Table 1 and Figure 5.

As shown in Figure 5, consecutive additions of  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  (222 $\mu\text{M}$  final concentration) to aortic rings  
25 pre-contracted with phenylephrine elicited a rapid and significant vasodilatation ( $P < 0.05$ ); the extent of relaxation was already pronounced after the first addition of the compound (45% more than control). Interestingly, after extensive washing, the  
30 phenylephrine-induced contraction was completely restored in control but not in  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$ -treated vessels indicating that this compound produces long-lasting effects.

The vasodilatory response mediated by metal carbonyls was almost totally abolished when reduced Mb (150 $\mu$ M), which avidly binds CO, was added to the buffer. Collectively, these findings are consistent with the  
5 fact that CO released from metal carbonyls possesses vasoactive properties.

As shown in Table 1,  $[\text{Ru}(\text{CO})_2(\text{DMSO})_2\text{Cl}_2]$  also produced vasodilatation although the effect was less pronounced compared to  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$ . Interestingly,  
10 while  $[\text{Ru}(\text{CO})_3\text{Cl}_2(\text{cytosine})]$  did not demonstrate any effect during the time duration of this experiment,  $[\text{Ru}(\text{CO})_3(\text{glycinato})\text{Cl}]$  elicited significant vasodilatation which is consistent with the high release of CO detected with the MbCO assay. Notably,  
15  $[\text{Fe}(\text{SPh})_2(2,2'\text{-bipyridine})(\text{CO})_2]$  which did not release any detectable CO to myoglobin, was still very effective in promoting vasorelaxation. On the other hand, the effect of  $[\text{Fe}(\text{SPh})_2(\text{H}_2\text{NCH}_2\text{CH}_2\text{NH}_2)(\text{CO})_2]$  was less evident.

**Table 1**

Treatment	% Relaxation		
	<i>1<sup>st</sup> addition</i>	<i>2<sup>nd</sup> addition</i>	<i>3<sup>rd</sup> addition</i>
Vehicle (DMSO)	5.7±0.9	11.4±1.1	18.1±2.5
[Ru(CO) <sub>3</sub> Cl <sub>2</sub> ] <sub>2</sub>	49.9±2.7*	66.2±3.2*	74.1±4.1*
[Ru(CO) <sub>3</sub> Cl <sub>2</sub> ] <sub>2</sub> + Mb	4.0±0.9 <sup>†</sup>	8.6±0.4 <sup>†</sup>	15.5±0.4 <sup>†</sup>
[Ru(CO) <sub>3</sub> Cl <sub>2</sub> ] <sub>2</sub> + ODQ	7.1±1.1 <sup>†</sup>	23.6±3.8* <sup>†</sup>	55.5±6.9* <sup>†</sup>

[Fe(SPh) <sub>2</sub> (H <sub>2</sub> NCH <sub>2</sub> CH <sub>2</sub> NH <sub>2</sub> )(CO) <sub>2</sub> ]	11	24.6	29.3

\* P < 0.01, compared to vehicle; <sup>†</sup> P < 0.01 compared to [Ru(CO)<sub>3</sub>Cl<sub>2</sub>]<sub>2</sub>.

Because CO is thought to modulate signal  
 5 transduction mechanisms via increased production of  
 cGMP, we investigated the effect of a selective  
 inhibitor of guanylate cyclase (ODQ, 10 μM) on vessel  
 contractility. As expected, ODQ considerably reduced the  
 vasodilatation observed after the first two additions of  
 10 [Ru(CO)<sub>3</sub>Cl<sub>2</sub>]<sub>2</sub>; however, it is of interest that the third  
 addition of [Ru(CO)<sub>3</sub>Cl<sub>2</sub>]<sub>2</sub> still elicited a substantial

vasodilatory action despite the presence of ODQ. Thus, the guanylate cyclase-cGMP pathway appears to be involved in the relaxation caused by this metal carbonyl complex.

5

#### **E. Expression of heme oxygenase in rat tissues**

As a background to the experiments below, we conducted the following procedure to demonstrate the effect of stimulating CO production endogenously by treating animals with hemin.

For immunohistochemistry analysis, sections of heart muscles (5  $\mu$ m thickness) were treated with 0.3% H<sub>2</sub>O<sub>2</sub> in methanol to block endogenous peroxidase activity. Immunohistochemical staining was performed using rabbit polyclonal antibody against HO-1 (1:1000 dilution) as previously described (23). The presence of HO-1 was indicated by the development of a brown color. For Northern blot analysis, cardiac tissue was ground in a mortar under liquid nitrogen and suspended in guanidinium thiocyanate lysis buffer. Total RNA was then extracted using a modification of the method described by Chomczynski and Sacchi (49). RNA was run on a 1.3% denaturing agarose gel containing 2.2 M formaldehyde and transferred onto a nylon membrane overnight. The membrane was hybridized using [ $\alpha$ -<sup>32</sup>P]dCTP-labelled cDNA probes to rat HO-1 and GAPDH genes and bands analyzed using a densitometer as previously described (23,50).

Hearts were removed from Lewis rats 24 h after treatment with vehicle (control) or hemin (75  $\mu$ mol/kg, i.p.) and immunostaining for HO-1 was assessed. For Northern blot analysis, rats were treated with hemin (75  $\mu$ mol/kg, i.p.) and hearts removed at different time

30

points to assess HO-1 mRNA levels (+ve, positive control).

Figure 7 confirms that HO-1 protein (7a) and mRNA (7b) are highly expressed in hearts 24 h after hemin treatment; interestingly, the immunostaining for HO-1 protein was primarily confined to the vessels of cardiac muscle (Figure 7a, right panel).

**F. Attenuation of vasoconstriction by metal carbonyls in perfused heart**

Additional experiments were conducted to determine the biological activity of metal carbonyls on vascular function *in vivo* and compare it with HO-1-derived CO, by monitoring their effects on changes in coronary perfusion pressure (CPP) of isolated rat hearts.

Langendorff heart preparations were performed using male Lewis rats (300-350 g) as previously described by our group (35). Hearts were excised, the aorta cannulated and retrograde perfusion was established at a constant flow of 15 ml/min using Krebs-Henseleit buffer (in mM: 119 NaCl, 4.7 KCl, 2.5 CaCl<sub>2</sub>, 1.66 MgSO<sub>4</sub>, 24.9 NaHCO<sub>3</sub>, 1.18 KH<sub>2</sub>PO<sub>4</sub>, 5.55 glucose, 2.00 sodium pyruvate, 0.5 EGTA) bubbled with 95% O<sub>2</sub> and 5% CO<sub>2</sub> at 37°C (pH 7.4). Coronary perfusion pressure (CPP), a parameter indicative of coronary vessel contractility, was continuously measured by a pressure transducer connected to the aortic cannula and data analyzed with an Acknowledge software (BIOPAC System Inc.).

Hearts removed either from control rats (vehicle-treated) or from animals that were pre-treated with the heme oxygenase-1 inducer hemin (75 µmol/kg, i.p.) the day before, were initially equilibrated for 20 min on the Langendorff apparatus and then perfused with L-NAME

(25  $\mu$ M final concentration) to elicit vasoconstriction. The extent of CPP increase by L-NAME was also monitored over time in hemin-treated animals that received a heme oxygenase inhibitor (SnPPiX, 40  $\mu$ mol/kg) 1 h prior to heart excision and in control hearts that were perfused with buffer supplemented with  $[\text{Mn}_2(\text{CO})_{10}]$  (13  $\mu$ M final concentration). Since  $[\text{Mn}_2(\text{CO})_{10}]$  releases CO only by photodissociation, Krebs buffer containing  $[\text{Mn}_2(\text{CO})_{10}]$  was exposed to a cold light source immediately before entering the aortic cannula.

Vasoconstriction was elicited by perfusion with L-NAME and the extent of CPP increase measured over time. As shown in Figure 6, L-NAME caused a time-dependent increase in CPP, which reached a maximum (3-fold) after 30 min. Notably, perfusion of hearts with light-stimulated  $[\text{Mn}_2(\text{CO})_{10}]$  (13  $\mu$ M) significantly delayed vasoconstriction and maintained CPP at much lower levels at the end of perfusion. When the buffer containing  $[\text{Mn}_2(\text{CO})_{10}]$  was not exposed to light, thus omitting the CO-induced release process, the extent of constriction mediated by L-NAME was unaffected (data not shown); in addition, perfusion with manganese chloride (negative control) had no effect on myocardial CPP (data not shown).

The effect observed with  $[\text{Mn}_2(\text{CO})_{10}]$  could be similarly reproduced by induction of HO-1 in heart tissue by pretreatment with hemin. It has previously been reported that treatment of rats with hemin results in increased production of cardiac bilirubin, which is equimolar to endogenously generated CO (35). The rise in CPP mediated by L-NAME in hemin-treated hearts was markedly attenuated ( $P < 0.05$ ), to an extent similar to that produced by  $[\text{Mn}_2(\text{CO})_{10}]$  (Figure 6); predictably,

the effect of hemin was completely reversed by tin protoporphyrin IX (SnPPIX), a heme oxygenase inhibitor. Thus, the vasoactive properties of the HO-1/CO pathway can be simulated by  $[\text{Mn}_2(\text{CO})_{10}]$ .

- 5        Results are means  $\pm$  s.e.m. of 6 independent experiments. \*  $P < 0.05$  vs. vehicle-treated group (control).

#### **G. Animal studies**

- 10        Since it has previously been reported that HO-1-derived CO also prevents acute hypertension *in vivo* (40), experiments were performed to examine the effectiveness of metal carbonyls in regulating mean arterial pressure in animals.

- 15        Lewis rats (280-350 g) were anaesthetised by intramuscular injection of 1 ml/kg Hypnorm (fentanyl 0.315 mg/ml and fluanisone 10 mg/ml) followed 5 min later by an intraperitoneal injection of 5 mg/kg diazepam. Specially designed femoral artery and venous  
20 catheters were then surgically implanted as previously described (40). The arterial cannula was connected to a Grass pressure transducer and blood pressure monitored continuously using a polygraph recorder. Experiments  
25 were conducted on anaesthetized animals and recordings were made within 30 min of the surgical procedure.

- Control rats (vehicle-treated) and animals that were pre-treated with hemin (75  $\mu\text{mol/kg}$ , i.p) 24 h prior to blood pressure monitoring were then administered with an intravenous injection of 30  $\mu\text{mol/Kg}$  L-NAME to elicit an  
30 increase in mean arterial pressure. The extent of blood pressure increase by L-NAME was also monitored over time in hemin-treated animals that received SnPPIX (40  $\mu\text{mol/kg}$ , i.p.) and in control rats previously injected

with  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  (60  $\mu\text{mol/kg}$ , i.v.). In these two groups, SnPPIX or  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  were administered to animals 1 h prior to L-NAME injection. Results are shown in Figure 8.

5            Intravenous infusion of L-NAME in rats produced a rapid and significant increase in blood pressure ( $P < 0.05$ ); this effect was markedly suppressed by pre-treatment of animals with a single infusion of  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  prior to L-NAME administration. Moreover,  
10 and in analogy with the data on coronary vasoconstriction in isolated hearts, treatment of animals with hemin resulted in a significant suppression of the L-NAME-mediated hypertensive responses, which once again was totally reversed by blockade of the heme  
15 oxygenase pathway with SnPPIX. Results are the means  $\pm$  s.e.m. of 5 independent experiments.  $*P < 0.05$  vs. vehicle-treated group (control). Collectively, these *in vivo* findings attest a consistent and reproducible biological activity of metal carbonyls through their  
20 ability to carry and deliver CO.

#### **H. Further studies on CO release**

The myoglobin assay procedure of section A above was carried out on many other metal-carbonyl complexes,  
25 to determine the amount of CO release and information on the kinetics of CO release. The compounds and the results are tabulated in Figs. 9a to 9f. The compounds include  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  also tested in section A and complexes related to it. The applicants' internal  
30 reference numbers are used for convenience.

To obtain the data in Figs. 9a to 9f the carbonyl compounds (CO-RMs) were solubilized in water or DMSO as indicated and added immediately to a solution of

myoglobin (66  $\mu$ M) in phosphate buffer (pH = 7.4). Two different concentrations were tested for each CO-RM (20 and 40  $\mu$ M) and the conversion of myoglobin to carbon monoxide myoglobin (MbCO) was measured

5 spectrophotometrically at different time points (0, 10, 20 and 30 min). MW = molecular weight. PPT indicates that a precipitate formed. N.D. = "not detectable".

The CO release data of section A above and Figs. 9a to 9f shows that selection of the ligands modulates CO  
10 release, both as to amount released and rate of release, permitting selection of release properties, which is important for targeting a specific biological effect.

**I. Effect of CO-RM-3 (Ru(CO)<sub>3</sub>Cl(glycinato)) on systemic**  
15 **blood pressure and heart rate in anaesthetised rats**

Adult male Sprague-Dawley rats (280 - 350 g, 8 - 10 weeks of age) were bred in-house at the Northwick Park Institute for Medical Research (Harrow, UK). Rats were housed in groups of 3 in cages under a 12 h cycle of  
20 day/night, with free access to drinking water and fed *ad libitum*. All surgical procedures were performed in compliance with U.K. Home Office regulations. Rats were anaesthetised in a polycarbonate chamber in a stream of Enflurane™ (Abbot, UK) in oxygen before being  
25 transferred onto a mask and continuously supplied with Enflurane™ throughout the experiment with an anaesthetic machine (Airmed, UK). During the surgical procedure the rats were kept at a constant body temperature of 37°C using a heat pad positioned underneath the operating  
30 surface. Specially designed femoral artery and venous catheters were then surgically implanted as previously described (see ref. 40). The catheter in the artery was

connected via a luer connector and a three-way tap to a pressure transducer (Gould model P231b, Statham, USA) for continuous mean arterial pressure (MAP) and heart rate (HR) monitoring. A purpose-built tail-cuff pressure transducer (ADInstruments, UK) was also placed on the tail of the rat and pressure transducer and tail cuff were connected to a polygraph recorder (Grass Model 7D, Astra-med, UK) pre-calibrated in millimetres of mercury (mmHg). An analogue output provided data for a computer-based data acquisition system (PowerLab™, ADInstruments, UK). The computer-based system was set to record mean arterial pressure (MAP), in mmHg, and heart rate (HR), in beats/min (bpm), for the duration of the experiment. A period of 20 minutes was allowed after surgery during which time anaesthetic supply was adjusted so that each animal had a stable resting MAP of around 80 mmHg ( $n=16$ , mean = 81.5 mmHg). Once a stable pressure had been reached, each catheter was flushed with saline containing heparin and no further changes were made to the anaesthetic supply.  $\text{Ru}(\text{CO})_3\text{Cl}(\text{glycinato})$  (CO-RM-3) was prepared in stock solutions of 20, 60 and 120  $\mu\text{moles.ml}^{-1}$  by solubilizing the compound in saline. *Cis*- $\text{RuCl}_2(\text{DMSO})_4$ , which does not contain any carbonyl groups, was used as a 'negative control'. CO-RM-3 (or the negative control) was then infused into the animal via the femoral vein catheter as a bolus so that the final concentration infused was 10, 30 or 60  $\mu\text{moles.kg}^{-1}$  body weight. Throughout the experiment MAP and HR were continuously recorded and monitored. Although concentrations of 10, 30 and 60  $\mu\text{moles.kg}^{-1}$  were infused into each animal, the resulting concentrations in the animal were cumulative. Therefore, the final

concentration attained in the animal was 10, 40 and 100  $\mu\text{moles.kg}^{-1}$ , respectively.

The results are presented in Table 2, where the data shown represents samples taken at baseline (just before infusion of the compound) and directly after administration of 10, 30 and 60  $\mu\text{moles.kg}^{-1}$  of the compound. All data are mean  $\pm$  SEM.  $n = 3$  independent experiments.  $*P < 0.05$  vs. baseline.

*Cis*- $\text{RuCl}_2(\text{DMSO})_4$  (control) had no significant effects on either HR or MAP at any of the concentrations used (10, 30 or 60  $\mu\text{moles.kg}^{-1}$ ). Even after the final (60  $\mu\text{moles.kg}^{-1}$ ) infusion of *Cis*- $\text{RuCl}_2(\text{DMSO})_4$ , the MAP ( $81 \pm 4$  mmHg) and HR ( $256 \pm 9$  bpm) were well preserved compared to baseline measurements ( $80 \pm 2$  mmHg and  $257 \pm 7$  bpm, respectively). There was a marginal increase ( $5.5 \pm 1$  mmHg) in MAP during the administration of each bolus of the compound. However, this effect is believed to be associated with a volume increase since it also occurred when saline was infused during the inserting procedure. In contrast, administration of  $\text{Ru}(\text{CO})_3\text{Cl}(\text{glycinato})$  resulted in a concentration-dependent transient decrease in MAP followed by a return to baseline over a period of 10 min; with 10, 30 and 60  $\mu\text{moles.kg}^{-1}$  bolus infusions resulting in  $6 \pm 2$ ,  $8 \pm 3$  and  $14 \pm 0.3$  ( $P < 0.05$ ) mmHg decreases, respectively. As before, HR remained unchanged ( $253 \pm 23$  bpm) compared to baseline ( $270 \pm 20$  bpm). These data demonstrate that CO liberated from CO-RM-3 can modulate blood pressure and can be used therapeutically to control acute and chronic hypertensive responses *in vivo*. These data parallel the evidence that endogenous CO generated from activated

heme oxygenase-1 is a potent vasodilator and suppresses acute hypertension *in vivo* (see ref. 23 and 40).

**J. Effect of Ru(CO)<sub>3</sub>Cl(glycinato) on cardiac transplant rejection in mice**

Hearts from male BALB/c mouse (25-30 g) were used as donor organs for transplantation into male CBA mice (25-30 g). Mice were housed in groups of 3 in cages under a 12 h cycle of day/night, with free access to drinking water and fed *ad libitum*. All surgical procedures were performed in compliance with U.K. Home Office regulations. Animals were anaesthetized by an intraperitoneal injection of ketamine/xylazine during all procedures. The surgical technique involved the transplantation of the cardiac allograft into the recipient's neck as previously described (51). Graft survival was assessed daily by palpation, and rejection was diagnosed by cessation of ventricular contractions.

Ru(CO)<sub>3</sub>Cl(glycinato) was dissolved in 0.1 ml saline and administered intraperitoneally. All doses are 40 mg/kg of Ru(CO)<sub>3</sub>Cl(glycinato). The donors received two doses of Ru(CO)<sub>3</sub>Cl(glycinato) respectively at 1 day and 15 min prior to cardiac harvest. The recipients received doses of Ru(CO)<sub>3</sub>Cl(glycinato) at 1 day before surgery, 30 min prior to cardiac reperfusion and 1 h after transplantation (Day 0). Thereafter, graft recipients received a daily dose of Ru(CO)<sub>3</sub>Cl(glycinato) from day 1 to day 8 (inclusive) post-transplant. In the control group, recipients received an equivalent dose of saline (vehicle) 1 day before and each day (days 1 to 8) after cardiac transplantation. Carprofen (0.01 mg) was given subcutaneously for pain relief immediately after transplantation to all animals. The results of this study are shown in Figure 10. n = 5 for each group. \*p<0.002 vs. control. BALB/c hearts trasplanted into

CBA mice following treatment with saline (control group) underwent rejection very rapidly. 100% of hearts stopped beating within 9 days of transplantation. In contrast, the survival time of hearts transplanted into mice receiving  $\text{Ru}(\text{CO})_3\text{Cl}(\text{glycinato})$  was significantly prolonged ( $p < 0.002$ ) with 100% of hearts still beating 18 days after transplantation. At 25 days after heart transplantation, 60% of mice treated with  $\text{Ru}(\text{CO})_3\text{Cl}(\text{glycinato})$  still did not show any sign of rejection ( $p < 0.002$ ) and at 30 days 40% of transplanted hearts were still viable. These data demonstrate that  $\text{Ru}(\text{CO})_3\text{Cl}(\text{glycinato})$  is very effective in prolonging the survival of murine cardiac grafts and attenuating organ rejection. The result is in parallel with recently published reports showing that mice treated with CO gas (by inhalation) are significantly less susceptible to graft rejection in a model of mouse-to-rat cardiac transplant (51).

Based on the findings above on CO release and vasorelaxation, the data in this section indicates that CO liberated from the carbonyl complex mediates the anti-rejection process.

**K. Effect of  $\text{Ru}(\text{CO})_3\text{Cl}(\text{glycinato})$  on nitric oxide production in macrophages following endotoxin challenge**

The signaling molecule nitrogen monoxide (NO), which is generated in mammals by a family of constitutive (nNOS and eNOS) and inducible (iNOS) NO synthase enzymes, plays an essential regulatory role in a variety of physiological and pathophysiological processes that take place within the cardiovascular, nervous and immune systems (52). Overproduction of NO

has been established as a potent cytotoxic weapon in host defense against infection, inflammation and cancer. Considerable amounts of NO can originate from activated iNOS when appropriately induced by cytokines, endotoxins or lipopolysaccharide (LPS), oxygen free radicals or other stressful stimuli (53). In particular, macrophages are a specific target of pro-inflammatory stimuli as they highly express iNOS and can generate excessive amounts of NO to modulate important cytostatic/bactericidal actions. From unpublished data, it has been postulated that induction of the heme oxygenase-1 (HO-1)/bilirubin/CO pathway represents a counter-regulatory system against the deleterious effects elicited by overproduction of NO. Specifically, both CO and bilirubin may interfere with NO generation by acting as inhibitors of NOS activity and scavenger of NO, respectively. CO gas has been shown to inhibit NOS activity in various tissues (54), and it has been suggested that bilirubin can directly interact with NO and NO-related species (55).

The present study was undertaken to assess the effect of Ru(CO)<sub>3</sub>Cl(glycinato) (CO-RM-3) on the production of NO from endotoxin-stimulated macrophages. Mouse RAW 264.7 macrophages were cultured in 24 wells using DMEM medium. Confluent cells were incubated for 24 h with *E. Coli* lipopolysaccharide (LPS, 3 µg/ml) in the presence or absence of increasing concentrations of CO-RM-3 (10, 50 and 100 µM). Control cells were exposed to culture medium alone. Nitrite in the culture medium was measured as an index of NO production using the Griess reagent method (56). Cell viability was also assessed in macrophages 24 h after treatment with the

various agents as described in reference 47. Treatment of macrophages with LPS caused a significant increase in nitrite levels ( $p < 0.05$ ) after 24 h incubation (see Fig. 11, where bars represent the mean  $\pm$  S.E.M. of 6 independent experiments.  $*p < 0.05$  vs. control;  $^{\dagger}p < 0.05$  vs. LPS. The presence of CO-RM-3 significantly attenuated nitrite generation in a concentration dependent manner. As shown in Fig. 12 (where bars represent the mean  $\pm$  S.E.M. of 6 independent experiments), these treatments did not affect cell viability as no toxic effect was observed at the end of the incubation period.

These data indicate in the ability of CO released from CO-RM-3 to prevent the inflammatory response in macrophages by inhibiting the production of iNOS-derived NO. Furthermore, and in line with the beneficial effects shown by CO-RM-3 on blood pressure and cardiac graft rejection, these results suggest a potential therapeutic application of water-soluble CO carriers in the modulation of vascular- and inflammatory-related pathological states.

### **L. Syntheses**

Synthetic methods for obtaining compounds of Figs. 9a to 9f tested for CO release will now be described. Purity of the product has not been investigated in detail. Stereoisomers are expected to be present.

#### **Preparation of $\text{Ru}(\text{CO})_3\text{Cl}(\text{NH}_2\text{CH}_2(\text{CH}_2\text{SH})\text{CO}_2)$ [ $M_r$ 340.5]**

L-Cysteine complex. Reference number: CO-RM-26

$[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  (0.129g, 0.25 mmol) and L-cysteine (0.039g, 0.50 mmol) were placed under nitrogen in a

round bottomed flask. Methanol (75 cm<sup>3</sup>) and sodium ethoxide (0.034g, 0.50 mmol) were added and the reaction allowed to stir for 18 hours. The solvent was then removed under pressure and the yellow residue  
5 redissolved in THF, filtered and excess 40-60 light petroleum added. The yellow solution was evaporated down to give an orange solid (0.120g, 70%).

**Preparation of Ru(CO)<sub>3</sub>Cl(NH<sub>2</sub>CH<sub>2</sub>CO<sub>2</sub>) [M<sub>R</sub> 294.5]**

10 Glycine complex. Reference number: CO-RM-3

[Ru(CO)<sub>3</sub>Cl<sub>2</sub>]<sub>2</sub> (0.129g, 0.25 mmol) and glycine (0.039g, 0.50 mmol) were placed under nitrogen in a round bottomed flask. Methanol (75 cm<sup>3</sup>) and sodium ethoxide (0.034g, 0.50 mmol) were added and the reaction  
15 allowed to stir for 18 hours. The solvent was then removed under pressure and the yellow residue redissolved in THF, filtered and excess 40-60 light petroleum added. The yellow solution was evaporated down to give a pale yellow solid (0.142g, 96%).

20

**Preparation of Ru(CO)<sub>3</sub>Cl(NH<sub>2</sub>CH(CHMeCH<sub>2</sub>CH<sub>3</sub>)CO<sub>2</sub>) [M<sub>R</sub> 350.5]**

DL-Isoleucine complex. Reference number: CO-RM-38

[Ru(CO)<sub>3</sub>Cl<sub>2</sub>]<sub>2</sub> (0.129g, 0.25 mmol) and DL-isoleucine (0.066g, 0.50 mmol) were placed under nitrogen in a  
25 round bottomed flask. Methanol (75 cm<sup>3</sup>) and sodium ethoxide (0.034g, 0.50 mmol) were added and the reaction allowed to stir for 18 hours. The solvent was then removed under pressure and the yellow residue redissolved in THF, filtered and excess 40-60 light  
30 petroleum added. The yellow solution was evaporated down to give a yellow solid (0.086g, 49%).

**Preparation of  $\text{Ru}(\text{CO})_3\text{Cl}(\text{NH}_2\text{CH}(\text{CH}_2\text{OH})\text{CO}_2)$  [ $M_R$  324.5]**

L-Serine complex. Reference number: CO-RM-39.

[ $\text{Ru}(\text{CO})_3\text{Cl}_2$ ]<sub>2</sub> (0.129g, 0.25 mmol) and L-serine (0.053g, 0.50 mmol) were placed under nitrogen in a round bottomed flask. Methanol (75 cm<sup>3</sup>) and sodium ethoxide (0.034g, 0.50 mmol) were added and the reaction allowed to stir for 18 hours. The solvent was then removed under pressure and the yellow residue redissolved in THF, filtered and excess 40-60 light petroleum added. The yellow solution was evaporated down to give a pale yellow solid (0.095g, 59%)

**Preparation of  $\text{Ru}(\text{CO})_3\text{Cl}(\text{NH}_2\text{CH}(\text{CH}_3)\text{CO}_2)$  [ $M_R$  308.5]**

L-Alanine complex. Reference number: CO-RM-40.

[ $\text{Ru}(\text{CO})_3\text{Cl}_2$ ]<sub>2</sub> (0.129g, 0.25 mmol) and L-alanine (0.045g, 0.50 mmol) were placed under nitrogen in a round bottomed flask. Methanol (75 cm<sup>3</sup>) and sodium ethoxide (0.034g, 0.50 mmol) were added and the reaction allowed to stir for 18 hours. The solvent was then removed under pressure and the yellow residue redissolved in THF, and filtered. The solution was evaporated down to give an orange solid (0.145g, 94%).

**Preparation of  $\text{Ru}(\text{CO})_3\text{Cl}(\text{NH}_2\text{CH}(\text{CH}_2\text{CH}_2\text{CONH}_2)\text{CO}_2)$  [ $M_R$  365.5]**

L-Glutamine complex. Reference number: CO-RM-42.

[ $\text{Ru}(\text{CO})_3\text{Cl}_2$ ]<sub>2</sub> (0.129g, 0.25 mmol) and L-glutamine (0.073g, 0.50 mmol) were placed under nitrogen in a round bottomed flask. Methanol (75 cm<sup>3</sup>) and sodium ethoxide (0.034g, 0.50 mmol) were added and the reaction allowed to stir for 18 hours. The solvent was then removed under pressure and the yellow residue redissolved in THF and filtered. The solution was

evaporated down to give a yellow oil which solidified under high vacuum to give a pale yellow solid (0.170g, 93%).

5 **Preparation of  $\text{Ru}(\text{CO})_3\text{Cl}(\text{NH}_2\text{CH}(\text{CH}_2\text{CH}_2\text{NHC}(=\text{NH})\text{NH}_2)\text{CO}_2)$**   
**[M<sub>R</sub> 393.5]**

L-Arginine complex. Reference number: CO-RM-43.

[Ru(CO)<sub>3</sub>Cl<sub>2</sub>]<sub>2</sub> (0.129g, 0.25 mmol) and L-arginine (0.087g, 0.50 mmol) were placed under nitrogen in a  
10 round bottomed flask. Methanol (75 cm<sup>3</sup>) and sodium ethoxide (0.034g, 0.50 mmol) were added and the reaction allowed to stir for 18 hours. The solvent was then removed under pressure and the yellow residue redissolved in THF/MeOH (4:1) and filtered. The  
15 solution was evaporated down to given an orange solid (0.185g, 94%).

**Preparation of  $\text{Ru}(\text{CO})_3\text{Cl}(\text{NH}_2\text{CH}(\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}_2)\text{CO}_2)$**   
**[M<sub>R</sub> 365.5]**

20 L-Lysine complex. Reference number: CO-RM-46.

[Ru(CO)<sub>3</sub>Cl<sub>2</sub>]<sub>2</sub> (0.129g, 0.25 mmol) and L-lysine (0.073g, 0.50 mmol) were placed under nitrogen in a round bottomed flask. Methanol (75 cm<sup>3</sup>) and sodium ethoxide (0.034g, 0.50 mmol) were added and the reaction  
25 allowed to stir for 18 hours. The solvent was then removed under pressure and the yellow residue redissolved in THF/MeOH (3:1) and filtered. The solution was evaporated down to give a yellow oil which solidified under high vacuum to given an orange solid  
30 (0.163g, 89%).

**Preparation of  $\text{Ru}(\text{CO})_3\text{Cl}(\text{NH}_2\text{CH}(\text{CH}(\text{CH}_3)_2)\text{CO}_2$  [M<sub>R</sub> 336.5]**

L-Valine complex. Reference number: CO-RM-67.

[Ru(CO)<sub>3</sub>Cl<sub>2</sub>]<sub>2</sub> (0.129g, 0.25 mmol) and L-valine (0.059g, 0.50 mmol) were placed under nitrogen in a round bottomed flask. Methanol (75 cm<sup>3</sup>) and sodium ethoxide (0.034g, 0.50 mmol) were added and the reaction allowed to stir for 18 hours. The solvent was then removed under pressure and the yellow residue redissolved in THF and filtered. Excess 40-60 light petroleum was added and the solution evaporated down to given a white solid (0.114g, 68%).

**Preparation of Ru(CO)<sub>3</sub>Cl(NH<sub>2</sub>CH{CH(OH)CH<sub>3</sub>}CO<sub>2</sub>) [M<sub>R</sub> 338.5]**

L-Threonine complex. Reference number: CO-RM-74.

[Ru(CO)<sub>3</sub>Cl<sub>2</sub>]<sub>2</sub> (0.129g, 0.25 mmol) and L-threonine (0.060g, 0.50 mmol) were placed under nitrogen in a round bottomed flask. Methanol (75 cm<sup>3</sup>) and sodium ethoxide (0.034g, 0.50 mmol) were added and the reaction allowed to stir for 18 hours. The solvent was then removed under pressure and the yellow residue redissolved in THF and filtered. Excess 40-60 light petroleum was added and the solution evaporated down to give a white solid (0.149g, 88%).

**Preparation of [Fe(η-C<sub>5</sub>H<sub>5</sub>)(CO)<sub>3</sub>]Cl [M<sub>R</sub> 240.5]**

Reference number: CO-RM-70.

A sodium amalgam was prepared by, under nitrogen in a Schlenk tube, dissolving sodium metal (2.04g) in mercury (18 cm<sup>3</sup>). This was allowed to cool to room temperature and tetrahydrofuran (40 cm<sup>3</sup>) added. Then [FeCp(CO)<sub>2</sub>]<sub>2</sub> (7.08g, 20.3 mmol) in tetrahydrofuran (60 cm<sup>3</sup>) added and the flask shaken vigorously for 45 minutes.

Then into a large 3-necked flask purged with nitrogen, THF (300 cm<sup>3</sup>) and ethyl chloroformate (40 mmol, 4.34g, 3.84 cm<sup>3</sup>) were placed and cooled to 0°C. The red-yellow solution of cleaved dimer was then transferred  
5 into the round bottomed flask and allowed to stir for one hour at low temperature before being concentrated in volume. The red-brown residue was extracted with benzene (5 x 20 cm<sup>3</sup>), the extracts filtered, and HCl gas blown through the solution for 15 minutes. An immediate  
10 precipitation was observed, the solution was reduced in volume and the orange precipitate collected, washed with diethyl ether (20 cm<sup>3</sup>) and dried. (4.84g, 50%).

**Preparation of [Fe( $\eta$ -C<sub>5</sub>H<sub>5</sub>)(CO)<sub>3</sub>]PF<sub>6</sub> [M<sub>R</sub> 350]**

15 Reference number: CO-RM-71.

[Fe( $\eta$ -C<sub>5</sub>H<sub>5</sub>)(CO)<sub>3</sub>]Cl (3.00g, 12.5 mmol) was dissolved in water (50 cm<sup>3</sup>) and sodium hexafluorophosphate (2.00g, 1eq) in water (50 cm<sup>3</sup>) added. An orange precipitate was immediately formed, the reaction stirred for 15 minutes  
20 and the orange precipitate collected under suction (3.04g, 70%).

**Preparation of Ru(CO)<sub>3</sub>Cl<sub>2</sub>(guanosine) [M<sub>R</sub> 540]**

Reference number: CO-RM-17.

25 [Ru(CO)<sub>3</sub>Cl<sub>2</sub>]<sub>2</sub> (0.129g, 0.25 mmol) and guanosine (0.142g, 0.50 mmol) were placed under nitrogen in a round bottomed flask. Methanol (75 cm<sup>3</sup>) was added and the reaction allowed to stir for 18 hours. The solution was then filtered and reduced in volume to approximately  
30 10 cm<sup>3</sup>. Excess diethyl ether was added and the white precipitate formed allowed to settle out in the freezer overnight. The solvent was pipetted off to leave a

white solid which was dried under high vacuum (0.130g, 48%).

**Preparation of  $[\text{Ru}(\text{CO})_3\text{Cl}(\text{guanosine})_2]/\text{Cl}$  [ $M_R$  824]**

5 Reference number: CO-RM-18.

$[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  (0.129g, 0.25 mmol) and guanosine (0.284g, 1.00 mmol) were placed under nitrogen in a round bottomed flask. Methanol (75 cm<sup>3</sup>) was added and the reaction allowed to stir for 18 hours. The solution  
10 was then filtered and reduced in volume to approximately 10 cm<sup>3</sup>. Excess diethyl ether was added and the white precipitate formed allowed to settle out in the freezer overnight. The solvent was pipetted off to leave a white solid which was dried under high vacuum (0.220g,  
15 53%).

**Preparation of  $\text{Ru}(\text{CO})_3\text{Cl}_2(\text{triacetyl-guanosine})$  [ $M_R$  666]**

Reference number: CO-RM-29.

$[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  (0.129g, 0.25 mmol) and 2, 3, 5  
20 -triacetylguanosine (0.205g, 0.50 mmol) were placed under nitrogen in a round bottomed flask. Methanol (75 cm<sup>3</sup>) was added and the reaction allowed to stir for 18 hours. The solution was then filtered and reduced in volume to approximately 10 cm<sup>3</sup>. Excess diethyl ether was  
25 added and the white precipitate formed allowed to settle out in the freezer overnight. The solvent was pipetted off to leave a white solid which was dried under high vacuum (0.212g, 63%).

30 **Preparation of  $\text{Ru}(\text{CO})_3\text{Cl}_2(\text{guanine})$  [ $M_R$  408]**

Reference number: CO-RM-22.

[Ru(CO)<sub>3</sub>Cl<sub>2</sub>]<sub>2</sub> (0.129g, 0.25 mmol) and guanine (0.076g, 0.50 mmol) were placed under nitrogen in a round bottomed flask. Tetrahydrofuran (75 cm<sup>3</sup>) was added and the reaction allowed to stir for 18 hours. The solution was then reduced in volume to approximately 10 cm<sup>3</sup>. Excess 40-60 light petroleum was added and the precipitate formed allowed to settle out in the freezer overnight. The solvent was pipetted off to leave a pale yellow solid which was dried under high vacuum (0.082g, 39%).

**Preparation of [Ru(CO)<sub>3</sub>Cl(guanine)<sub>2</sub>]Cl [M<sub>R</sub> 558]**

Reference number: CO-RM-23.

[Ru(CO)<sub>3</sub>Cl<sub>2</sub>]<sub>2</sub> (0.129g, 0.25 mmol) and guanine (0.152g, 1.00 mmol) were placed under nitrogen in a round bottomed flask. Tetrahydrofuran (75 cm<sup>3</sup>) was added and the reaction allowed to stir for 18 hours. The solution was then reduced in volume to approximately 10 cm<sup>3</sup>. Excess 40-60 light petroleum was added and the precipitate formed allowed to settle out in the freezer overnight. The solvent was pipetted off to leave a cream solid which was dried under high vacuum (0.170g, 61%).

**Preparation of *fac*-RuCl<sub>2</sub>(CO)<sub>3</sub>(THF) [M<sub>R</sub> 328]**

Reference number: CO-RM-11.

[Ru(CO)<sub>3</sub>Cl<sub>2</sub>]<sub>2</sub> (0.380g, 0.74 mmol) and tetrahydrofuran (5 cm<sup>3</sup>) were placed in a conical flask and the yellow solution stirred for 15 minutes. Then the solvent was removed under reduced pressure leaving a yellow oil which upon standing solidified. Addition of diethylether (20 cm<sup>3</sup>) accompanied by sonication afforded

a white precipitate and yellow solution. The solid was collected and dried under vacuum (0.134g, 28%).

**Preparation of  $[\text{RuCl}_2(\text{CO})_2]_n[\text{M}_R \text{ unknown}]$**

5 Reference number: CO-RM-10.

$\text{RuCl}_3 \cdot x\text{H}_2\text{O}$  (5.00g), concentrated hydrochloric acid (25 cm<sup>3</sup>) and formic acid (25 cm<sup>3</sup>) were placed in a 3-necked round bottomed flask and the mixture refluxed for 18 hours. The clear yellow solution was then reduced in  
10 volume to leave a yellow/orange precipitate, which was transferred into a Soxhlet thimble and extracted overnight with methanol. This solution was then reduced in volume to give an orange oil which solidified under high vacuum to afford an orange precipitate (5.30g).

15

**Preparation of  $\text{Ru}(\text{CO})_3(\text{O}(\text{CH}_2\text{CO}_2)_2)[\text{M}_R \text{ 317}]$**

Diglycolic acid complex. Reference number: CO-RM-99

$[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  (0.129g, 0.25 mmol) and diglycolic acid (0.067g, 0.50 mmol) were placed under nitrogen in  
20 a round bottomed flask. Methanol (75 cm<sup>3</sup>) and sodium ethoxide (0.068g, 1.00 mmol) were added and the reaction allowed to stir for 18 hours. The solvent was then removed under pressure and the yellow residue redissolved in THF, filtered and excess 40-60 light  
25 petroleum added. The yellow solution was evaporated down to give a white solid (0.142g, 85%).

**Preparation of  $\text{Ru}(\text{CO})_3(\text{NH}(\text{CH}_2\text{CO}_2)_2)[\text{M}_R \text{ 317}]$**

Iminodiacetic acid complex. Reference number: CO-RM-97

30  $[\text{Ru}(\text{CO})_3\text{Cl}_2]_2$  (0.129g, 0.25 mmol) and iminodiacetic acid (0.066g, 0.50 mmol) were placed under nitrogen in a round bottomed flask. Methanol (75 cm<sup>3</sup>) and sodium

ethoxide (0.068g, 1.00 mmol) were added and the reaction allowed to stir for 18 hours. The solvent was then removed under pressure and the yellow residue redissolved in THF/MeOH (4:1), filtered and excess 40-60  
5 light petroleum added. The yellow solution was evaporated down to give an off-white solid (0.140g, 89%).

Syntheses suitable for CO-RM-1a, CO-RM-1b and the  
10 negative controls for these compounds are in reference 57. Synthesis of CO-RM-16 is found in reference 58.

While the invention has been described in conjunction with the exemplary embodiments described above, many equivalent modifications and variations will  
15 be apparent to those skilled in the art when given this disclosure. Accordingly, the exemplary embodiments of the invention set forth above are considered to be illustrative and not limiting. Various changes to the described embodiments may be made without departing from  
20 the spirit and scope of the invention.

**CLAIMS:**

1. A pharmaceutical composition, for delivery of carbon monoxide to a physiological target, comprising a metal carbonyl compound or pharmaceutically acceptable salt thereof and at least one pharmaceutically acceptable carrier, wherein the metal carbonyl makes available CO suitable for physiological effect by at least one of the following means:
- 1) CO derived by dissociation of the metal carbonyl is present in the composition in dissolved form;
- 2) on contact with a solvent the metal carbonyl releases CO;
- 3) on contact with a tissue, organ or cell the metal carbonyl releases CO;
- 4) on irradiation the metal carbonyl releases CO.
2. A pharmaceutical composition according to claim 1, wherein the metal carbonyl compound is a complex of at least one of Fe, Mn, Ru, Rh, Ni, Mo or Co with at least one carbonyl ligand.
3. A pharmaceutical composition according to claim 1 or claim 2, wherein the metal is bound to at least one group other than CO.
4. A pharmaceutical composition according to claim 3, wherein the group other than CO is a modulatory group, which modulates the solubility of the compound and/or the release of CO from the compound.

5. A pharmaceutical composition according to any one of claims 1 to 4 adapted for administration by an oral, intravenous, subcutaneous, nasal, inhalatory, intramuscular, intraperitoneal or suppository route.

5

6. A pharmaceutical composition for delivery of CO, comprising as active ingredient a compound of the formula  $M(CO)_x A_y$  where x is at least one, y is at least one, M is a metal, the or each A is an atom or group bonded to M by an ionic, covalent or coordination bond, and in the case where  $y > 1$  each A may be the same or different, or a pharmaceutically acceptable salt of such a compound.

10

7. A pharmaceutical composition according to claim 6 wherein M is a transition metal.

15

8. A pharmaceutical composition according to claim 6 or claim 7, wherein A is selected from halogens, groups having N, P, O or S atoms providing lone electron pairs for coordination bonding to M, and conjugated carbon groups.

20

9. A pharmaceutical composition according to any one of claims 6 to 8 adapted for delivery by an oral, intravenous, subcutaneous, nasal, inhalatory, intramuscular, intraperitoneal or suppository route.

25

10. A method of introducing CO to a mammal as a physiologically effective agent comprising the step of administering a pharmaceutical composition according to any one of claims 1 to 9.

30

11. A method according to claim 10, for the stimulation of guanylate cyclase activity.

12. A method according to claim 10 or claim 11, for  
5 stimulating neurotransmission or vasodilation, or for the treatment of any of hypertension, radiation damage, endotoxic shock, inflammation, an inflammatory-related disease, hyperoxia-induced injury, apoptosis, cancer, transplant rejection, arteriosclerosis, post-ischemic  
10 organ damage, myocardial infarction, angina, haemorrhagic shock, sepsis, penile erectile dysfunction and adult respiratory distress syndrome.

13. Use of a metal carbonyl compound in the manufacture  
15 of a medicament for administration by an oral, intravenous, subcutaneous, nasal, inhalatory, intramuscular, intraperitoneal, or suppository route, for the stimulation of neurotransmission or vasodilation by CO as a physiologically effective agent, or for the  
20 treatment of any of hypertension, radiation damage, endotoxic shock, inflammation, inflammatory-related diseases, hyperoxia-induced injury, apoptosis, cancer, transplant rejection, arteriosclerosis, post-ischemic organ damage, myocardial infarction, angina,  
25 haemorrhagic shock, sepsis, penile erectile dysfunction and adult respiratory distress syndrome.

14. Use according to claim 13 wherein the metal carbonyl compound is a complex of at least one of Fe,  
30 Mn, Ru, Rh, Ni, Mo or Co with at least one carbonyl ligand.

15. Use of a metal carbonyl compound as set out in any one of claims 6 to 8 in the manufacture of a medicament for the stimulation of neurotransmission or  
5 vasodilation, or for the treatment of any of hypertension, radiation damage, endotoxic shock, inflammation, an inflammatory-related disease, hyperoxia-induced injury, apoptosis, cancer, transplant rejection, arteriosclerosis, post-ischemic organ damage,  
10 myocardial infarction, angina, haemorrhagic shock, sepsis, penile erectile dysfunction and adult respiratory distress syndrome.

16. A method of treating a viable mammalian organ  
15 extracorporeally comprising contacting the organ with a pharmaceutical composition according to any one of claims 6 to 8.

17. A metal carbonyl compound of the formula  
20  $M(CO)_x A_y B_z$  where  
M is Fe, Co or Ru,  
x is at least one,  
y is at least one,  
z is zero or at least one,  
25 each A is a ligand other than CO and is monodentate or polydentate with respect to M and is selected from the amino acids  
alanine  
arginine  
30 asparagine  
aspartic acid  
cysteine

glutamic acid  
glutamine  
glycine  
histidine  
5 isoleucine  
leucine  
lysine  
methionine  
phenylalanine  
10 proline  
serine  
threonine  
tryptophan  
tyrosine  
15 valine  
 $O(CH_2COO)_2$  and  
 $NH(CH_2COO)_2$ , and  
B is optional and is a ligand other than CO,  
excluding  $Fe(CO)_x A_y$  where A is cysteine or an ester  
20 of cysteine and  $Ru(CO)_x A_y$  where A is proline.

18. A pharmaceutical composition, for delivery of  
carbon monoxide to a physiological target, comprising a  
compound which is formic acid, a formate, a formate  
25 ester or amide, an oxalate or an oxalate ester or amide,  
or a pharmaceutically acceptable salt thereof, and at  
least one pharmaceutically acceptable carrier, wherein  
the compound makes available CO suitable for  
physiological effect.

19. A method of introducing CO to a mammal comprising the step of administering a pharmaceutical composition according to claim 18.

- 5 20. A method according to claim 19 for stimulating guanylate cyclase activity, neurotransmission or vasodilation, or for the treatment of any of hypertension, radiation damage, endotoxic shock, inflammation, an inflammatory-related disease,
- 10 hyperoxia-induced injury, apoptosis, cancer, transplant rejection, arteriosclerosis, post-ischemic organ damage, myocardial infarction, angina, haemorrhagic shock, sepsis, penile erectile dysfunction and adult respiratory distress syndrome.
